

Software Modernization Strategies

32 approaches to revitalize and
right-size your legacy system
according to business needs

Ignore It!

Leave your system alone as long as it
does its job well.

Not every legacy system needs attention. Some run reliably, cause no friction, and cost little to operate. Modernization for its own sake wastes resources and introduces risk into something that was working fine. The question is not "can we improve this?" but "should we?"

Keep It Alive!

Keep your legacy system running, but make it a conscious choice, not a habit.

Keep It Alive sits between Ignore It and Shut It Down. The system is past its prime and everyone knows it, but replacing or retiring it is not yet feasible. The strategy accepts the ongoing cost of operation as the lesser evil, and focuses on keeping the system stable enough to serve its remaining purpose without investing in improvements it will never need.

Delegate!

Hand off what is holding you back and focus on what actually matters.

Delegate describes the transfer of responsibility for parts of a software system to an external party, such as a vendor, a managed service provider, or a platform. This approach fits when internal teams lack the capacity, expertise, or strategic interest to handle certain tasks themselves. The goal is to free up internal resources by letting someone else own and operate what is not core to the organization.

Give It Away!

Open-source what you can no longer advance alone, and let the community share the load.

Give It Away describes the decision to release a software system or component as open source so that an external community can share in its maintenance and further development. It makes sense when the organization can no longer justify the cost of advancing the software alone, but the software still has value to others. The goal is to reduce the burden of solo maintenance while keeping the software alive and potentially benefiting from community contributions.

Sell It!

Sell your legacy system to someone for whom it is worth more than it is to you.

Sell It describes the transfer of ownership of a legacy system to another organization for whom it holds more strategic or commercial value. It makes sense when the system no longer fits the direction of the organization but still represents a functioning product with an existing user base. The goal is to realize value from the asset while relieving the organization of the ongoing cost and responsibility of maintenance.

Buy New!

Buy a ready-made solution when someone else has already solved your problem.

Buy New describes the decision to replace a legacy system with a commercially available off-the-shelf product rather than building or maintaining it in-house. This approach fits when a vendor solution already covers the required functionality well enough and the organization's needs are not significantly different from the general market. The goal is to eliminate the burden of custom development in areas that do not differentiate the business.

Shut It Down!

End your legacy system's operation in a planned, orderly, and drama-free way.

Shut It Down describes the planned decommissioning of a legacy system that is no longer needed or viable. This approach fits when the system's users, use cases, or business context have disappeared, or when keeping it running costs more than any remaining value it provides. The goal is to end the system's operation in an orderly way, ensuring data is preserved or migrated and dependencies are cleanly resolved.

Consolidate It!

Replace your zoo of systems with fewer,
more manageable units.

Consolidate It describes the reduction of redundant systems by merging multiple overlapping solutions into a smaller, more manageable set. This comes into play when an organization has accumulated several systems that serve the same purpose across different teams or departments. The goal is to reduce operational complexity, maintenance overhead, and the cost of keeping parallel systems alive.

Standardize It!

Define how your systems are built, connected, and operated, and end the chaos.

Standardize It describes the definition and enforcement of common patterns, conventions, and interfaces across a landscape of systems. It makes sense when different systems have been built in incompatible ways, making integration, onboarding, and maintenance unnecessarily difficult. The goal is to reduce variety in how systems are constructed and operated so that teams can move between them without relearning everything from scratch.

Harmonize It!

Align your systems, models, and processes so they work together without friction.

Harmonization means making systems that were built independently work together without replacing any of them. Instead of forcing uniformity, you create alignment at the boundaries: shared vocabulary, compatible data exchanges, and agreed-upon outcomes. Different systems stay different, but they stop contradicting each other.

Partner It!

Work with external partners to evolve
your system together.

Partner It describes working with an external organization to jointly evolve a software system, rather than handling all development internally or delegating it to a vendor. This approach fits when a system exceeds what one organization can reasonably advance alone, but the knowledge, risk, or investment is worth sharing with a partner. The goal is to pool capabilities and distribute the modernization effort across organizations.

Bring It Back!

Take back control of your system when outsourcing costs more than it delivers.

Bring It Back describes the decision to end an outsourcing arrangement and return software development to an internal team. This comes into play when the cost, inflexibility, or knowledge loss caused by external vendors outweighs the original benefits of delegation. The goal is to regain direct control over a system that is strategically important to the organization.

Rethink It!

Do not question your system, question the assumptions it was built on.

Rethink It describes the fundamental questioning of the assumptions that a legacy system was built on, rather than iterating on the system itself. It makes sense when the original problem the system was designed to solve has changed so significantly that incremental improvement would mean optimizing the wrong thing. The goal is to discover whether the right system is even being built before investing further in modernization.

Remodel It!

Align your system's structure with the domain as you understand it today.

Software structures encode the assumptions of the people who built them. Over time, those assumptions become outdated: the business evolves, teams reorganize, domain knowledge deepens. Remodeling closes the gap between how the system is structured and how the domain actually works today, making the code easier to read, change, and extend without touching what the system does.

Trim it down!

Remove what nobody needs anymore and
give your system its actual purpose
back.

Trim It Down describes the deliberate removal of features, dependencies, and code from a legacy system that are no longer needed. This comes into play when a system has grown beyond its actual purpose and the accumulated weight of unused or redundant parts is making it harder to understand and change. The goal is to restore focus by cutting everything that does not actively contribute to the system's core function.

Improve It!

Keep your system fit through continuous, unspectacular work before the debt catches up with you.

Improve It describes the ongoing, incremental investment in a legacy system to keep it healthy without pursuing a large-scale transformation. This is typically used when the system is fundamentally sound but has accumulated technical debt, outdated dependencies, or degraded code quality. The goal is to prevent further deterioration by continuously raising internal quality through small, steady improvements.

Convert it!

Keep your system's proven logic and only swap out the technology it lives in.

Convert It describes the translation of a legacy system from one technology to another while preserving its existing behavior and business logic. It becomes relevant when the underlying logic of a system is still sound but the language, framework, or runtime it runs on has become a liability. The goal is to move the system to a maintainable technology stack without rewriting the logic it has accumulated over time.

Fork It!

Split off part of your system and turn it into a standalone, independent solution.

Fork It describes the creation of an independent copy of a codebase that is then developed separately from the original. This comes into play when a part of the system needs to evolve in a fundamentally different direction, such as targeting a new market or use case, without constraining or disrupting the original. The goal is to give a distinct product or use case its own trajectory without the overhead of maintaining a shared codebase for diverging needs.

Repurpose It!

Deploy your system for a new audience
instead of maintaining it for a
shrinking market.

Repurpose It describes the redeployment of an existing system for a new audience, market, or use case that it was not originally designed for. This is typically used when the core capabilities of the system are a good fit for a different context, and the cost of adapting it is lower than building something new. The goal is to extend the useful life of the system by finding a new problem it can solve.

Salvage It!

Keep the valuable components of your legacy system and leave the rest behind.

Legacy systems are rarely uniformly bad. Beneath the outdated interfaces and tangled dependencies, there are often components that represent years of hard-won refinement: battle-tested business rules, algorithms tuned against real edge cases, data models that survived countless requirement changes. Salvaging means being selective, taking what has earned its place and leaving the rest behind.

Wrap it!

Leave the core untouched and only modernize how your system talks to the outside world.

Wrap It describes the addition of modern interfaces and integration layers around a legacy system without changing its internal logic. It becomes relevant when the core of a system still works but the way it communicates with the outside world is outdated, incompatible, or difficult to work with.

The goal is to make the system accessible to modern consumers and tooling without touching the code that runs underneath.

Replace it!

Build new when the old system is more
burden than value.

Replace It describes the complete rewrite of a legacy system from scratch, discarding the existing codebase entirely. It applies when the system has deteriorated beyond incremental improvement, or when technology and architecture are so misaligned with current needs that no other approach works.

The goal is to build a new system that serves today's requirements, guided by everything learned from the old one.

Divide It!

Cut your system along its natural boundaries so one change no longer puts the whole system at risk.

Divide It describes the decomposition of a large, tightly coupled system into smaller, independently deployable units. This is typically used when a monolithic system has grown to the point where changes in one area create unacceptable risk or delay in others. The goal is to establish clear boundaries between parts of the system so that each can be developed, deployed, and scaled on its own terms.

Extract!

Pull the knowledge out of your system before you take the next step.

Extract describes the process of recovering and documenting the knowledge embedded in a legacy system before taking further modernization steps. It becomes relevant when the system contains business rules, domain logic, or operational knowledge that exists nowhere else and would be lost if the system were replaced or rewritten without care. The goal is to make implicit knowledge explicit so that it can inform the next step.

Preserve it!

Preserve your system so you can still start it when needed, without actively maintaining it.

Some systems outlive their operational life but cannot simply be discarded. Legal obligations, audit trails, or historical records may require them to remain accessible for years. Preservation freezes the system in a runnable state, typically through containerization, emulation, or documented environment snapshots, so it can be started when needed without anyone actively maintaining it.

Replatform it!

Give your system a new foundation when the code is still good but what is underneath no longer is.

Replatform It describes the migration of a system to a new technical foundation, such as a different runtime, database, or cloud platform, while keeping the application logic largely intact. This is typically used when the infrastructure layer has become a bottleneck or a risk, but the application itself does not need to be rewritten. The goal is to give the system a more sustainable base without the cost and risk of a full replacement.

Rehost it!

Move your system to a new environment
and leave everything else as it is.

Rehosting, often called "lift and shift", moves a system to a new infrastructure environment with the application code untouched. It is the fastest modernization move available: no refactoring, no rearchitecting, no retraining. The trade-off is that whatever inefficiencies or constraints exist in the application itself travel with it to the new environment.

Upgrade Tools!

Bring your tooling up to date so legacy work becomes more efficient.

Upgrade Tools describes the modernization of the development toolchain, build systems, testing infrastructure, and operational tooling used to work with a legacy system. This approach works best when the tooling around a system is so outdated that it creates unnecessary friction, slows down feedback loops, or introduces risk in day-to-day work. The goal is to make working with the system less painful without changing the system itself.

Align Strategy!

Align your organization's strategic direction toward a realistic approach to legacy.

Align Strategy describes establishing a clear, shared direction for how an organization approaches legacy modernization. It applies when modernization efforts are driven by trend, gut feeling, or local initiative rather than by a coherent understanding of what the organization actually needs. The goal is to ensure that modernization investments are made intentionally and in proportion to the real strategic priorities of the business.

Reshape Org!

Reshape teams, responsibilities, and incentives so legacy work finally works well.

Technology alone does not modernize systems, people do. And people work inside organizational structures that either enable or obstruct good work. When team boundaries cut across natural system boundaries, when no one owns the hard parts, or when incentives reward new features over maintenance, modernization stalls regardless of the technical strategy chosen. Reshaping the organization means fixing the structural causes of that friction.

Upskill People!

Invest in the people you already have
before investing in new technology.

Upskill People describes the deliberate investment in the knowledge and capabilities of the people who work with a legacy system. This approach works best when the team lacks the skills needed to understand, maintain, or modernize the system effectively, and where that gap is a bigger obstacle than the state of the technology itself. The goal is to increase the team's ability to deal with the system before spending further on tooling or rewrites.

Improve Processes!

Improve not the system, but the way
your team works with it.

Improve Processes describes the modernization of the workflows and collaboration patterns a team uses to work with a legacy system, rather than changing the system itself. This approach works best when slow delivery, poor quality, or high friction are caused by how the team works rather than by the code. The goal is to remove process-level obstacles that prevent the team from working effectively with the system as it is.
